

# Photovoltaic panels directly carry DC loads

## Overview

---

A solar energy system produces direct current (DC). A stand-alone system with energy storage (a battery) will have more components than a. A photovoltaic (PV) cell, commonly called a solar cell, is a nonmechanical device that converts sunlight directly into electricity. Sunlight is composed of photons, or particles of solar energy. The two principal classifications are grid-connected or utility-interactive. The output of a PV module depends on sunlight intensity and cell temperature; therefore components that condition the DC (direct current) output and deliver it to batteries, grid, and/or load are required for a smooth operation of the PV system. When sunlight hits the solar cells in a panel, it causes electrons to be knocked loose from their atoms.

The movement of electrons, which all carry a negative charge, toward the front surface of the PV cell creates an imbalance of electrical charge between the cell's front and back surfaces. This imbalance, in turn, creates a voltage potential similar to the negative and positive terminals of a battery. Electrical conductors on the PV cell absorb the See more on eia.gov
