

What is DG in Microgrid

Overview

Distributed Generation (DG) refers to small, decentralized power sources located close to where the energy is used. Examples include rooftop solar, small wind turbines, natural gas turbines, and fuel cells. Key features of DG: Capacity is usually small (from a few kW up to a few MW). The Energy Commission, the State of California, its employees, contractors, and subcontractors make no warranty, express or implied, and assume no legal liability for the information in this report; nor does any party represent that the uses of this information will not infringe upon privately. Distributed generation is the local production of electricity using solar, wind, CHP, fuel cells, and energy storage near the point of use, reducing transmission losses and improving grid resilience. Because they are able to operate while the main grid is down, microgrids can strengthen grid resilience and help mitigate grid disturbances as well as function as a grid resource for faster system. With increasing autonomy of the microgrid and the growing load, DG allocation is a mandatory exercise. To analyse such a system, droop-based load flow is.

Microgrid Analysis and Case Studies Report

This "grid interdependence" microgrid structure is emerging as a model that could enable the widespread deployment of DG and microgrid control technology, and enhance grid resiliency (Table 1).
